

Perfusion MRI

M A Oghabian

Perfusion MRI

Exogenous

- Dynamic Contrast Enhanced (DCE, bolus passage)
 - GRE-EPI (T2* weighted)
- Dynamic Susceptibility Contrast (DSC, bolus tracking)
 - Spoiled Fast Gradient Echo (T1 Weighted)

Endogenous

- Arterial spin labeling (ASL)
-

Perfusion Weighted Imaging (DSC)

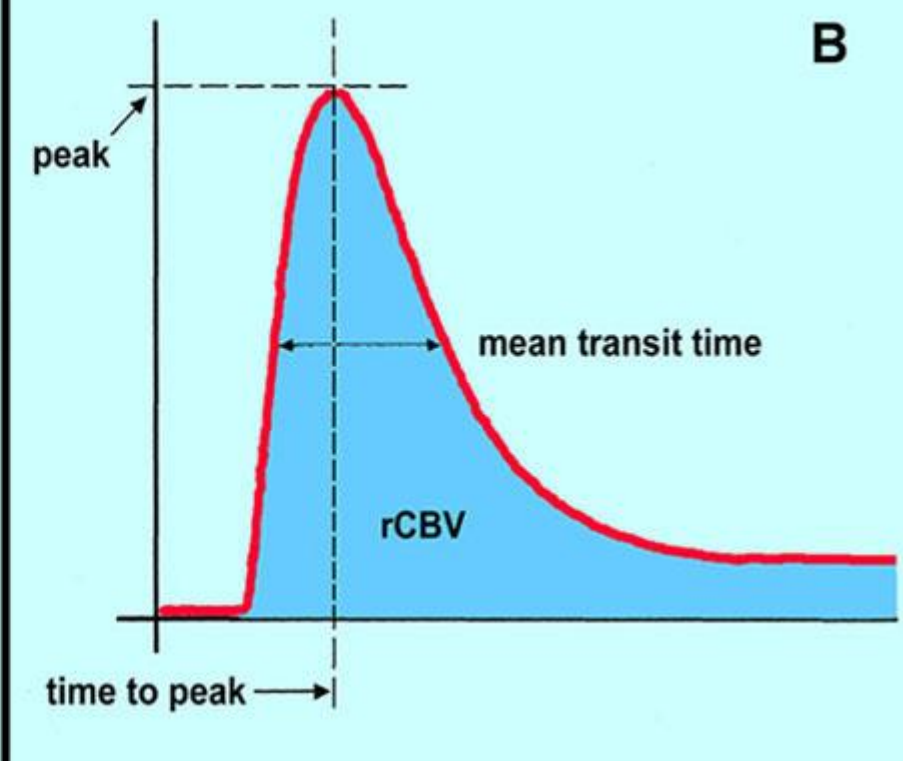

- Perfusion MRI techniques are sensitive to microscopic levels of blood flow.
- T2* susceptibility effects of gadolinium, rather than the T1 shortening effects make gadolinium a suitable agent.
- Susceptibility here refers to the loss of MR signal, most marked on T2* (gradient echo)- and T2 (SE), caused by the magnetic field-distorting effects of paramagnetic substances.

Perfusion Weighted Imaging (DSC)

- The ultimate goal of perfusion MRI is to measure the **blood flow** perfused in organ
- This flow corresponds to **microcirculatory** tissue perfusion rather than the flow of the main vascular axes
- This is expressed in **milliliters per 100 gram** of tissue per minute.

Cerebral perfusion MRI (Graph A)

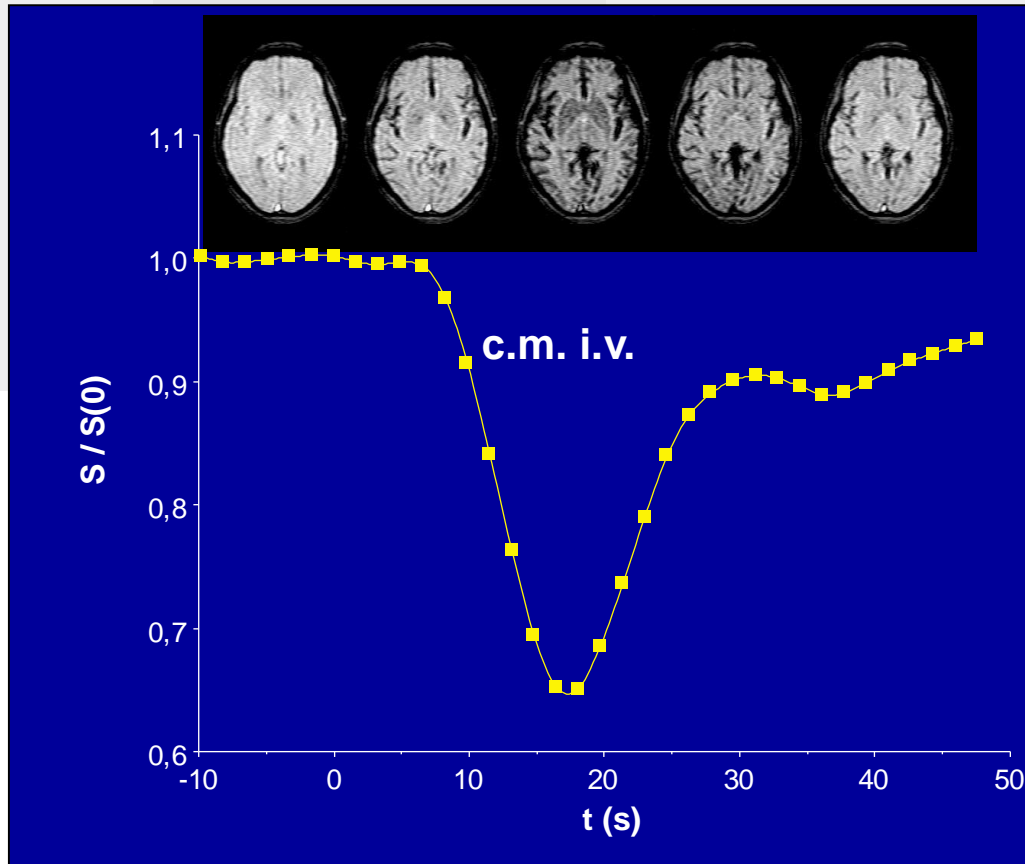

CT perfusion imaging (Graph B).

Graph A shows the effect of a bolus injection of a paramagnetic contrast agent, such as a gadolinium-based agent, as it passes through a single voxel as a function of time.

Graph B shows a similar but inverted response on CT perfusion study with the transit of iodinated contrast material through a sample, resulting in increased attenuation.

Perfusion-weighted MRI (PWI) measurement

Dynamic-susceptibility-weighted (DSC) MR imaging

Fast, repetitive T2*-weighted Sequences (GE) to follow the capillary passage of c.m.

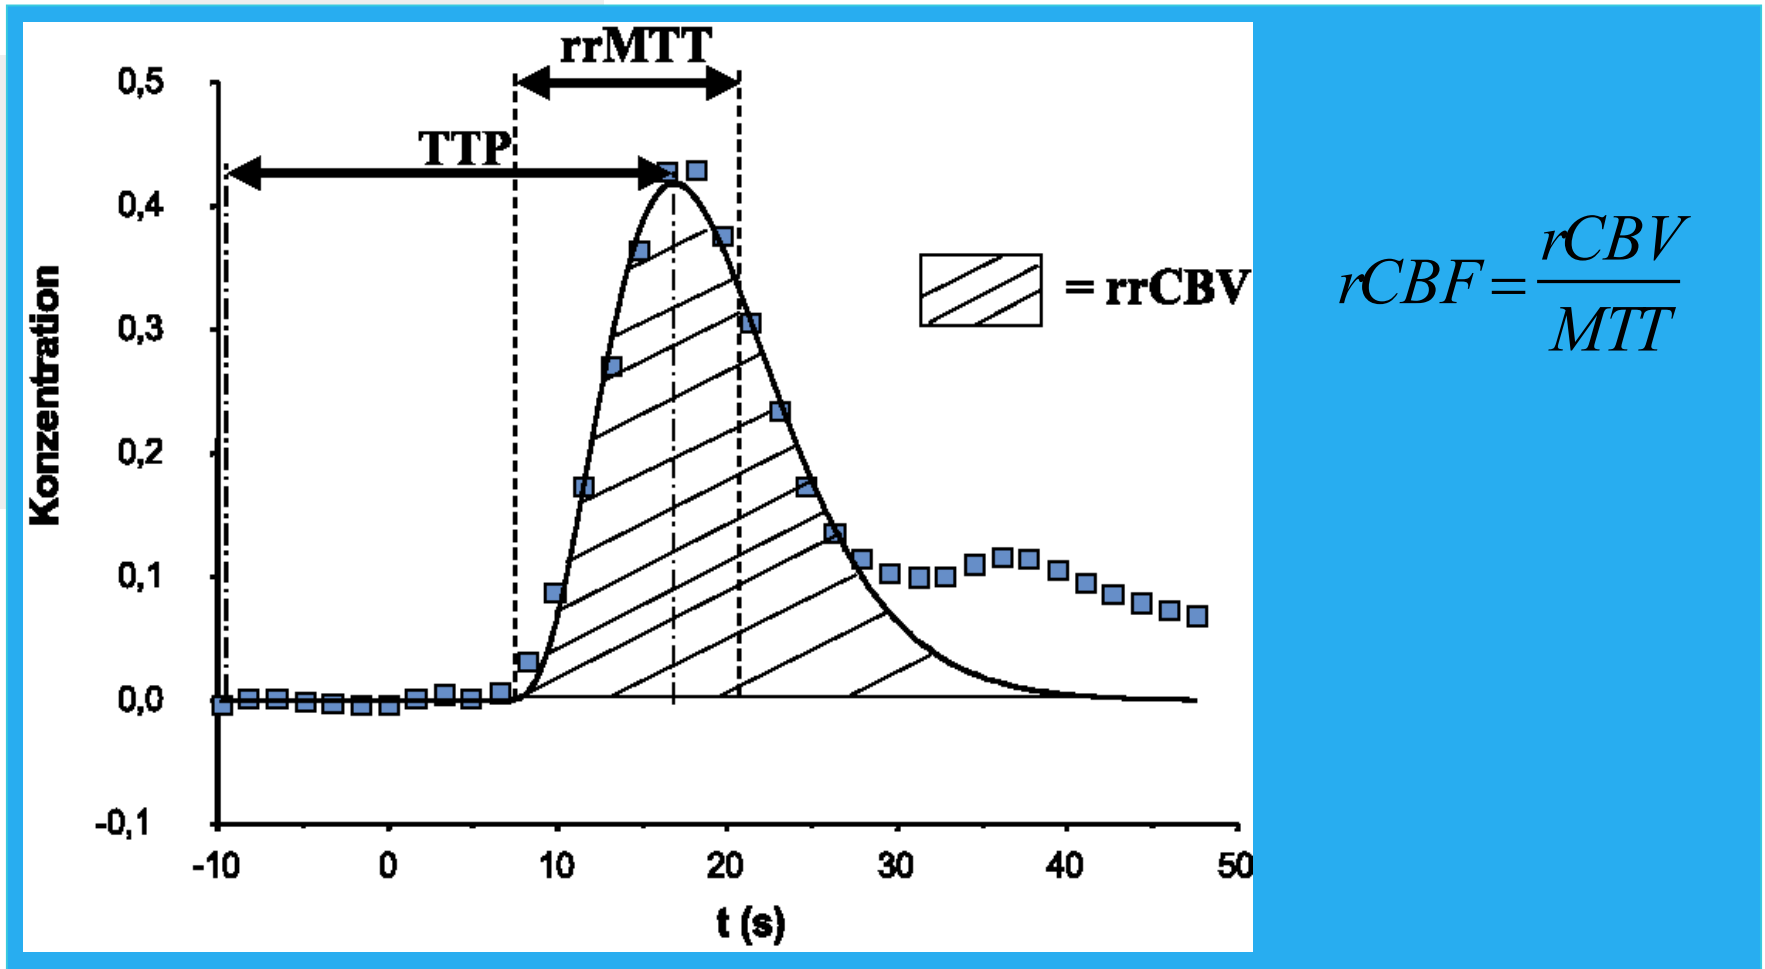

Susceptibility-derived signal decrease

Calculation of RELATIVE hemodynamic parameter maps

(a) Time: TTP, MTT

(b) Perfusion: rCBF, rCBV

Perfusion-weighted MRI (DSC-PWI) measurement

Comparison to contralateral side → regional relative CBF/CBV

Perfusion parameters

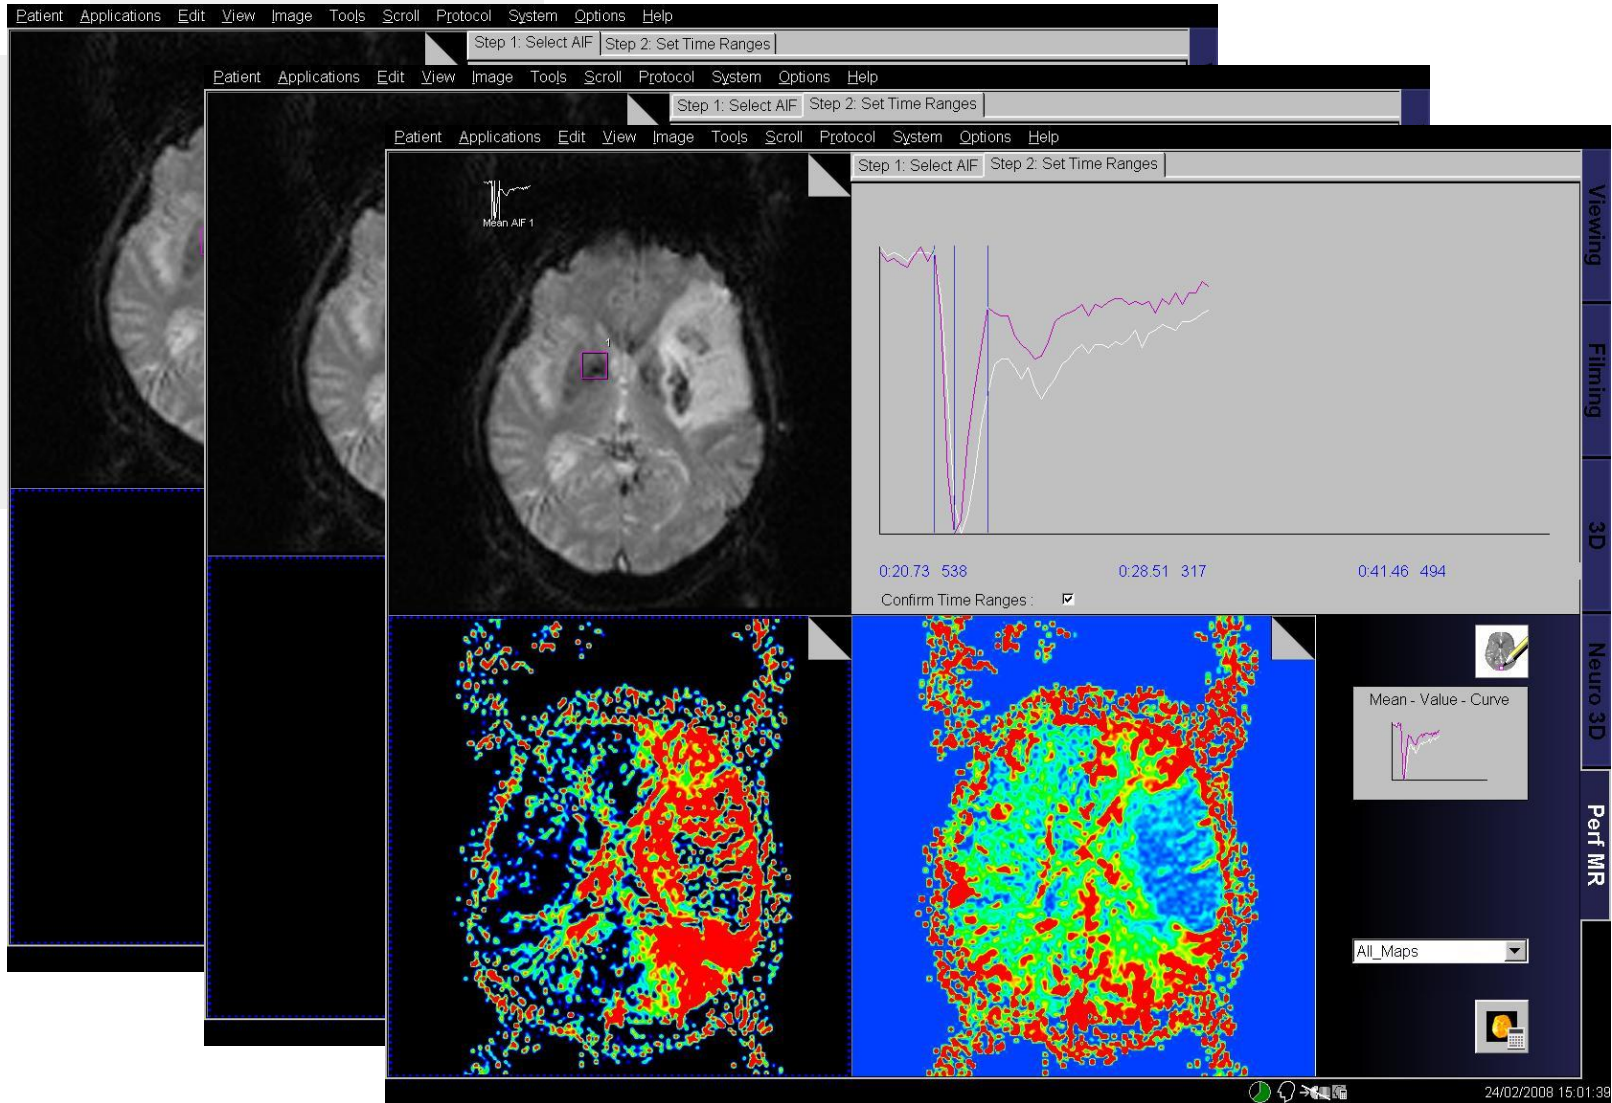

- These parameters are extracted by post-processing the signal curves, and are:
- **TA**: time of arrival of the contrast agent in the slice after injection
- **TTP** (Time To Peak): time corresponding to the maximum contrast variation
- **MTT** (mean transit time)
- **Peak amplitude**: percentage loss of intensity of the maximal signal
- **rCBV** (regional cerebral blood volume): The area below the decreasing signal curve
- **rCBF** (regional cerebral blood flow): The ratio $rCBV/MTT$.
- RCBV and rCBF are relative measurements, giving the calculation of ratios between pathological zone and healthy zone (which serves as a reference).

Perfusion MRI

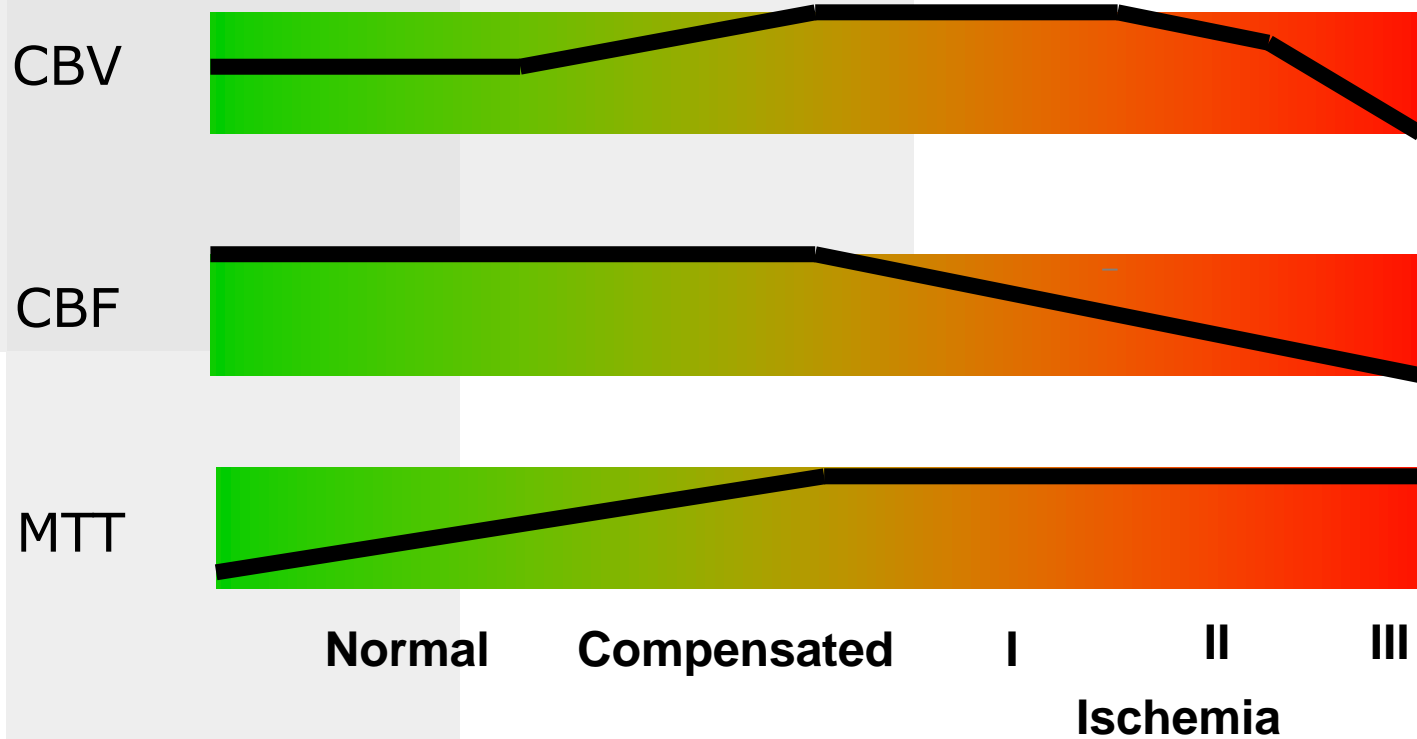

- Perfusion MRI is a technique for evaluation of microscopic blood flow in cerebral capillaries and venules.
- (Left) Perfusion of a [high grade brain tumor](#) demonstrates areas of increased capillary blood volume in tumor (red)
- (Right) Loss of perfusion due to Stroke

Perfusion-weighted MRI (PWI)

Perfusion-weighted MRI (PWI)

Relative CBV, CBF & MTT in ischemia

Perfusion-weighted MRI protocol for DSC

- Single dose of gadobenate dimeglumine
- Better S/N with 1-molar c.m. (> to 0.5-molar c.m.)
- T2*w-GRE; TR/TE, 1440/50 ms
- 20 slices, 60 measurements, 1.5min

Interfering effect of T1 in DSC

- Gadolinium chelates do not cross the normal **blood-brain barrier**. But in pathological conditions they cross.
- This effect reduce the T1 of the tissues and **increase signal** which contaminates the perfusion signal
- This leads to the risk of underestimating cerebral blood volume.

Non-contrast-agent based Perfusion: Arterial Spin Labeling (ASL)

- In ASL, **spins of inflowing blood** are sensitized to have different magnetic state to that of the static tissue, when flowing into the slices of interest.
- Contrast agents are not required for these techniques.
- A perfusion-weighted image can be generated by the **subtraction of an image** in which inflowing spins have been labeled from an image in which spin labeling has not been performed.

Concept of Arterial Spin Labeling (ASL)

- In ASL, endogenous arterial blood water is magnetically labeled instead of exogenously administered tracer, and the magnetic label decays with T1 instead of radioactive decay

clinical applications of ASL

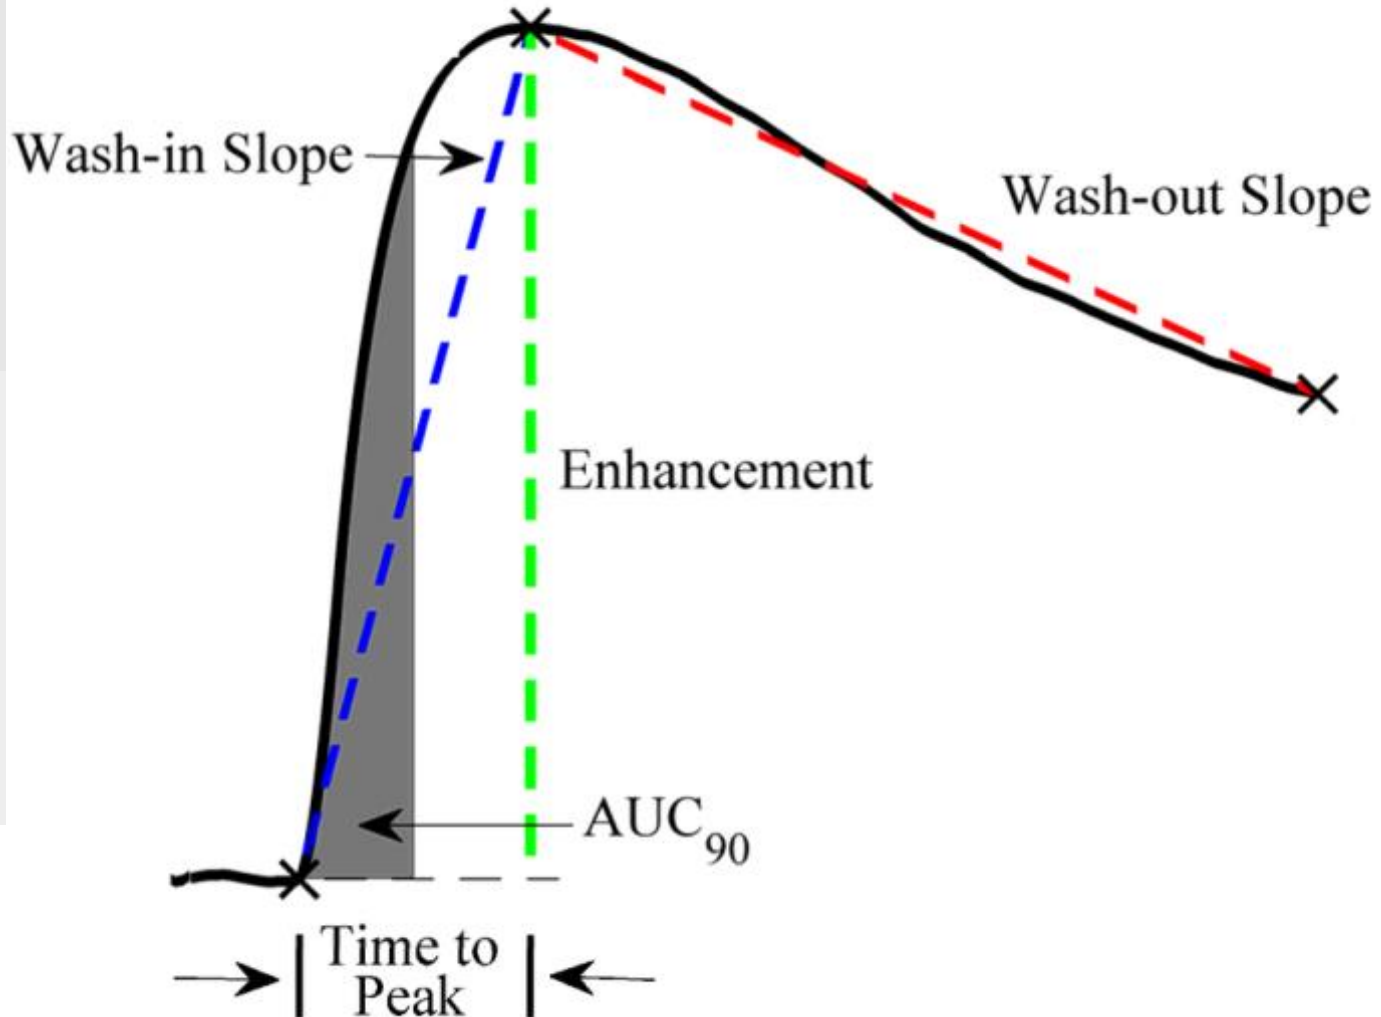

- **(A)**- Hypo-perfusion in an acute stroke (DWI and ASL)

- **(B)**- Hyper-perfusion in a glioblastoma (T2 and ASL)

Dynamic contrast enhanced imaging (DCE)

T1-weighted imaging with c.m. injection

Qualitative - shape of signal intensity (SI) data curve

Taylor and Reddick, Adv Drug Del Rev, 2000

DCE Perfusion Imaging

1. Contrast Injection Protocols
2. DCE MRI Acquisition Protocols
3. DCE MRI Quantification
 1. Arterial Input Function
 2. Relationship between T1 value and Contrast Concentration
 3. Pharmacokinetic Modeling

DCE imaging protocol

- Single dose of gadobenate dimeglumine
- 2D-T1w-GRE; TR/TE, 84/4.34 ms
- Repetitive measurements over 5min

Arterial Input Function (AIF)

Signal intensity change over time and location in the feeding artery.

AIF needs to be specified by user

AIF Can be averaged over multiple pixels and slices

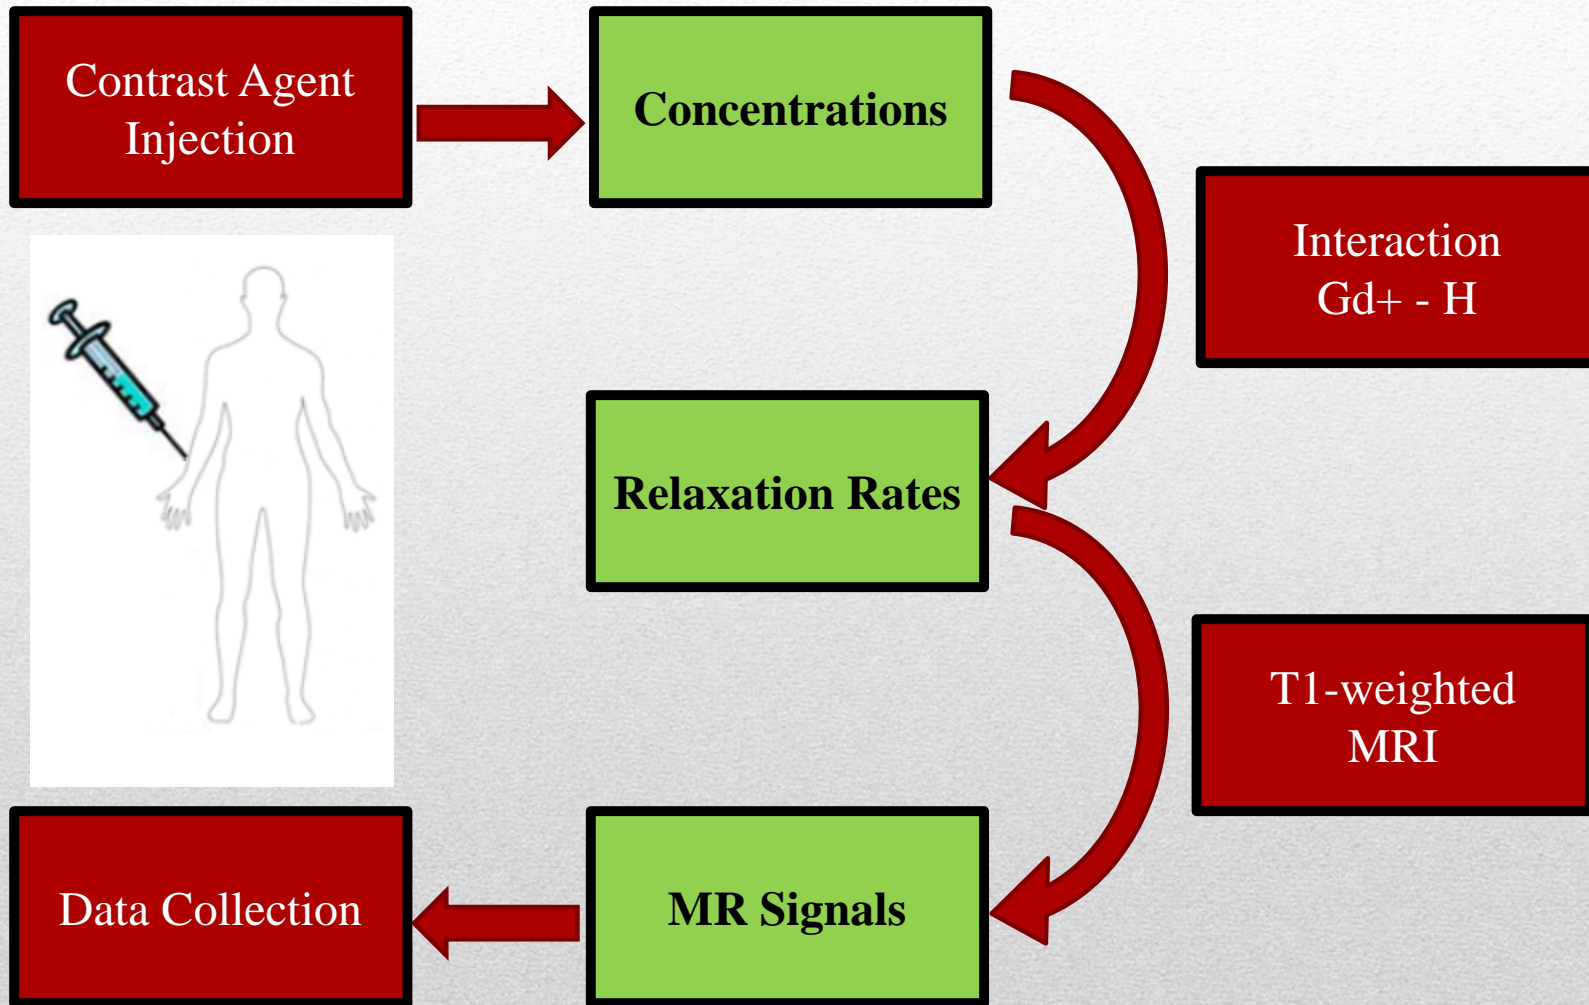

Automatic Search for AIF

- Global search within the imaging volume:
 - Select pixels based peak signal intensity, and uptake slope
- Select AIF from known Arteries

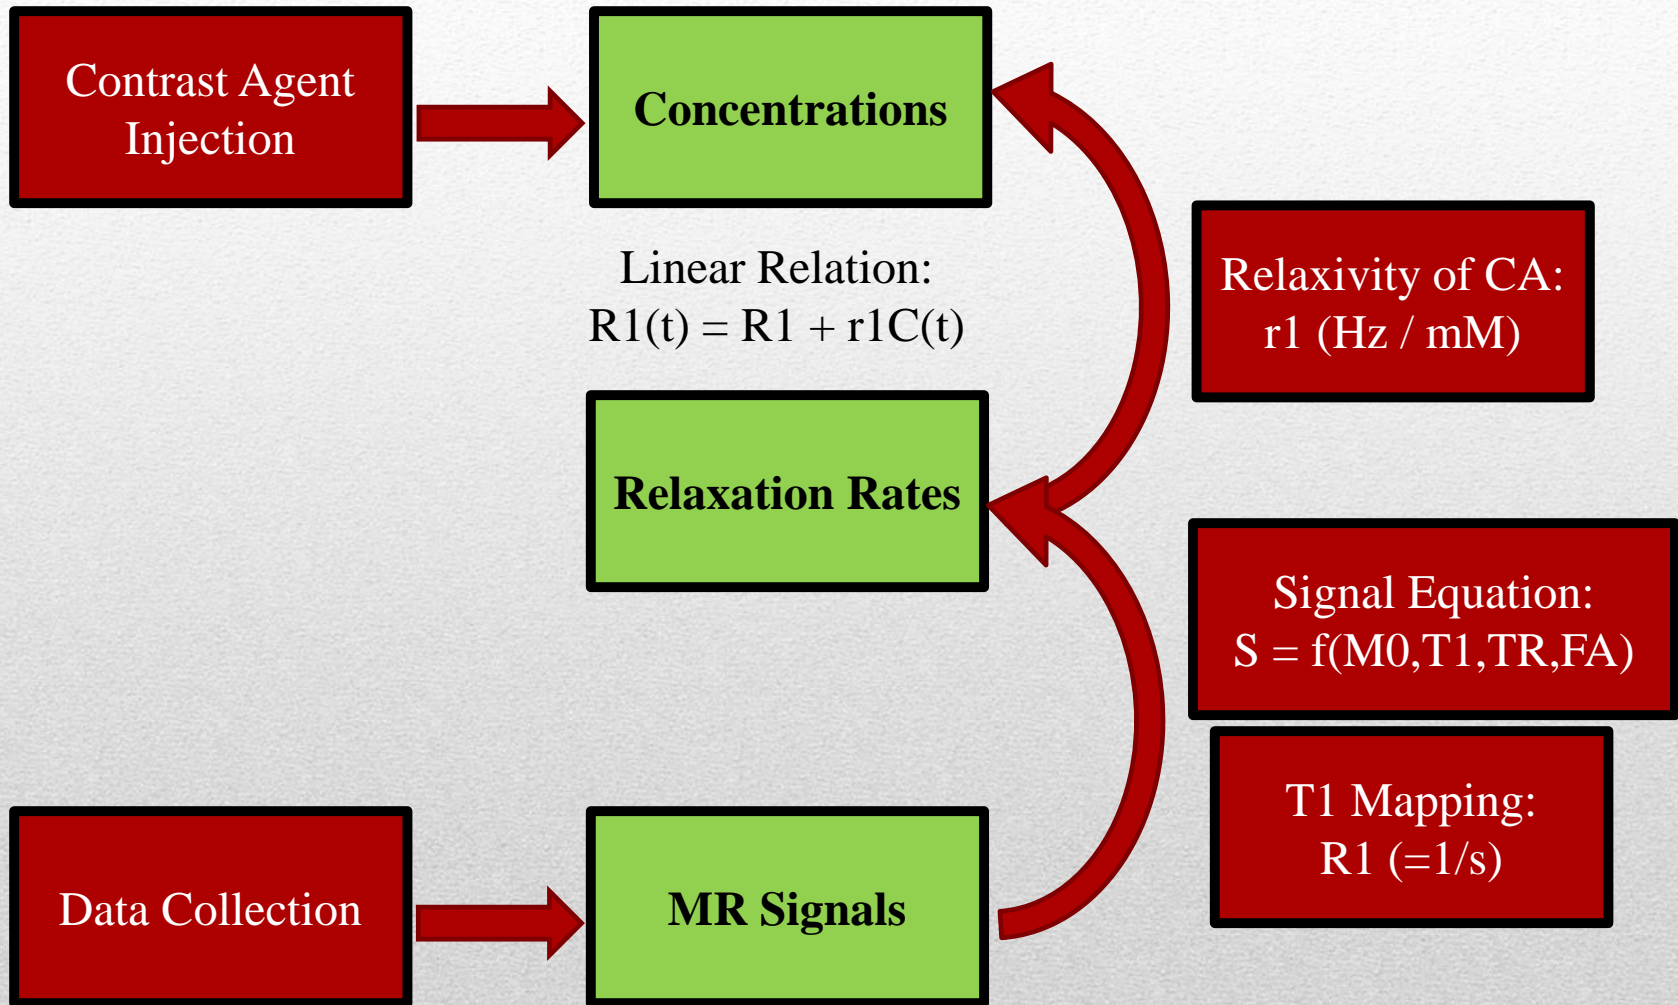

J. Chen et al Med Image Comput Comput Assist Interv. 2008; 11(Pt 1): 594–601

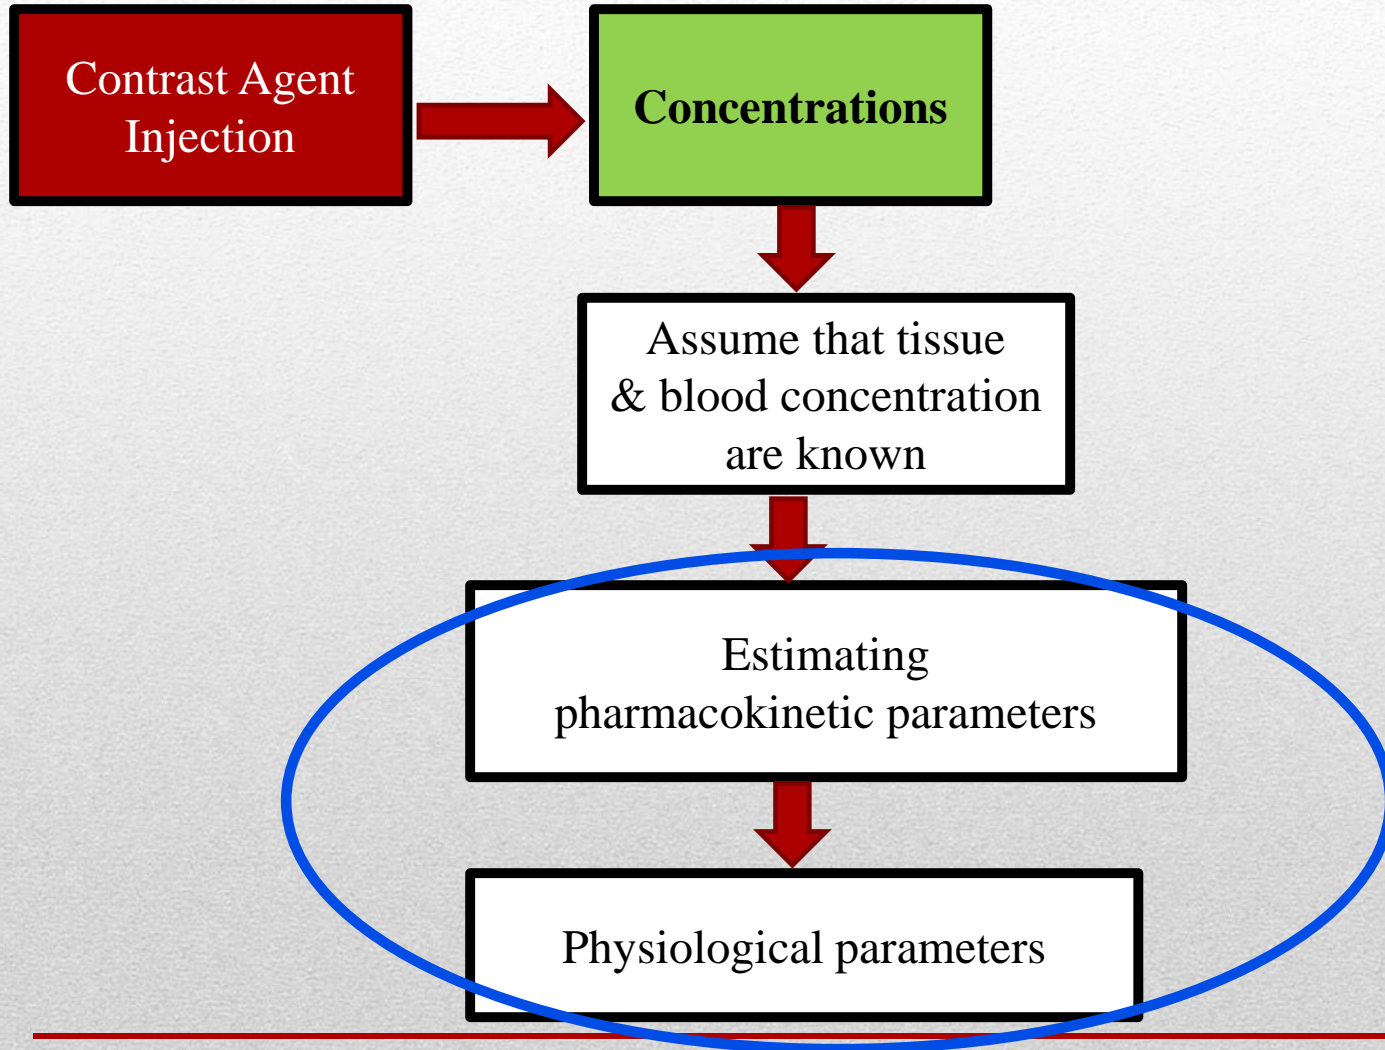

Calculation: T1w DCE MRI

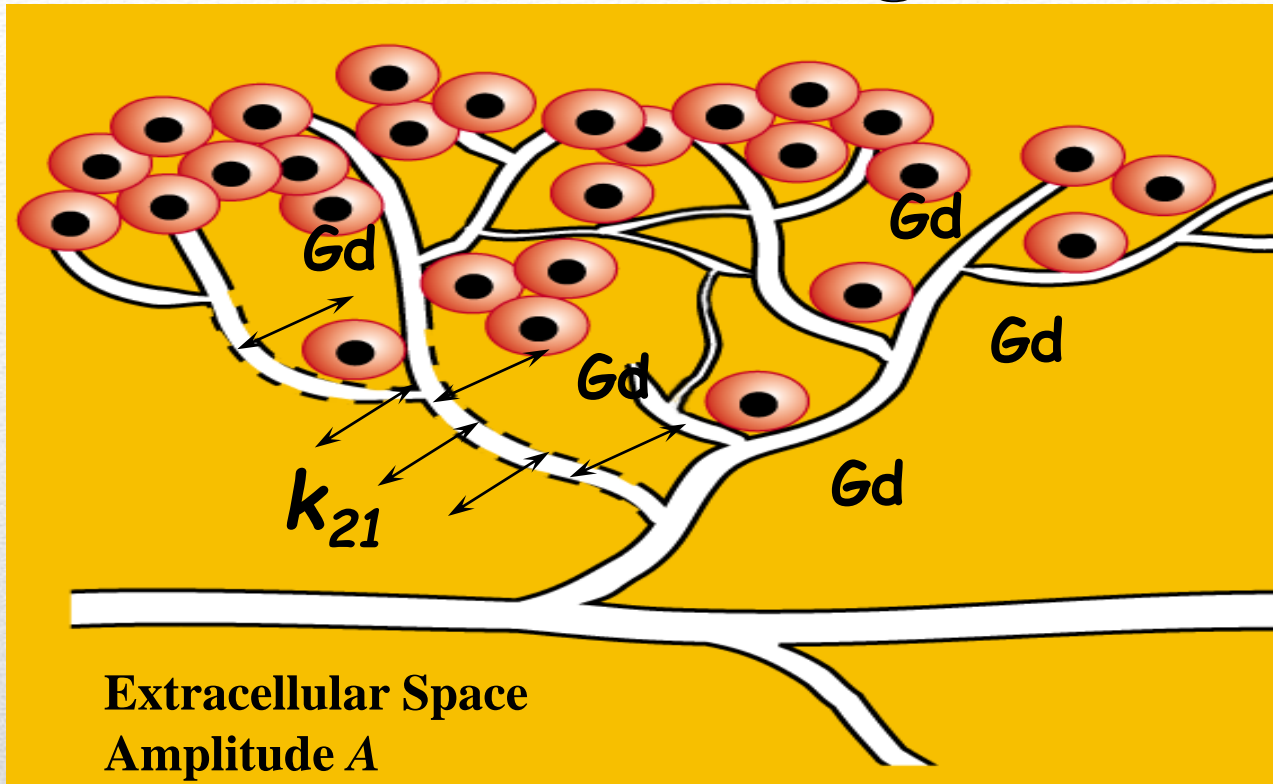

Calculation: T1w DCE MRI

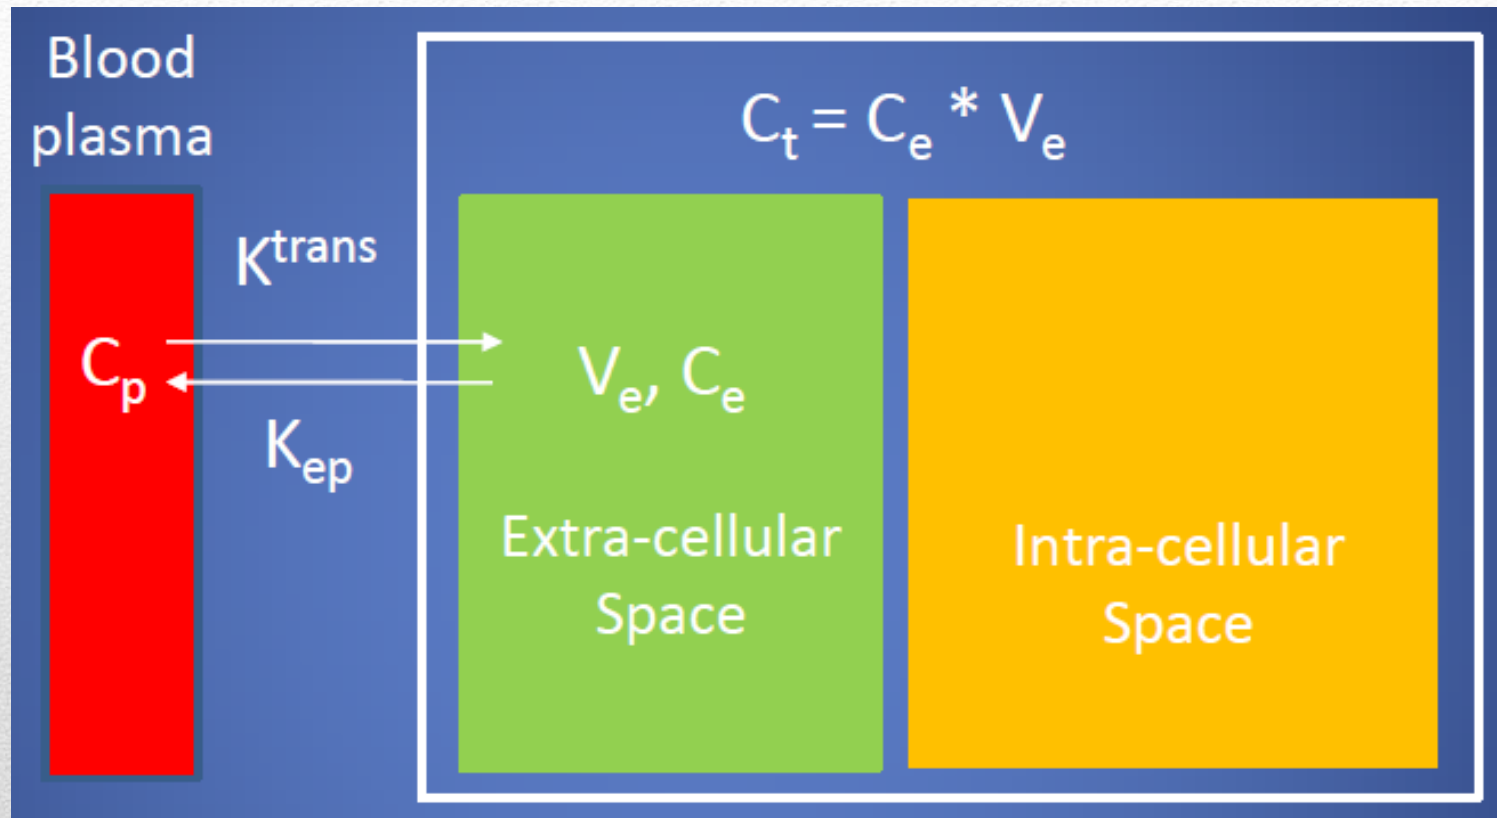

Calculation: T1w DCE MRI

Pharmacokinetic Modelling (Tofts Model)

Pharmacokinetic Modelling (Tofts Model)

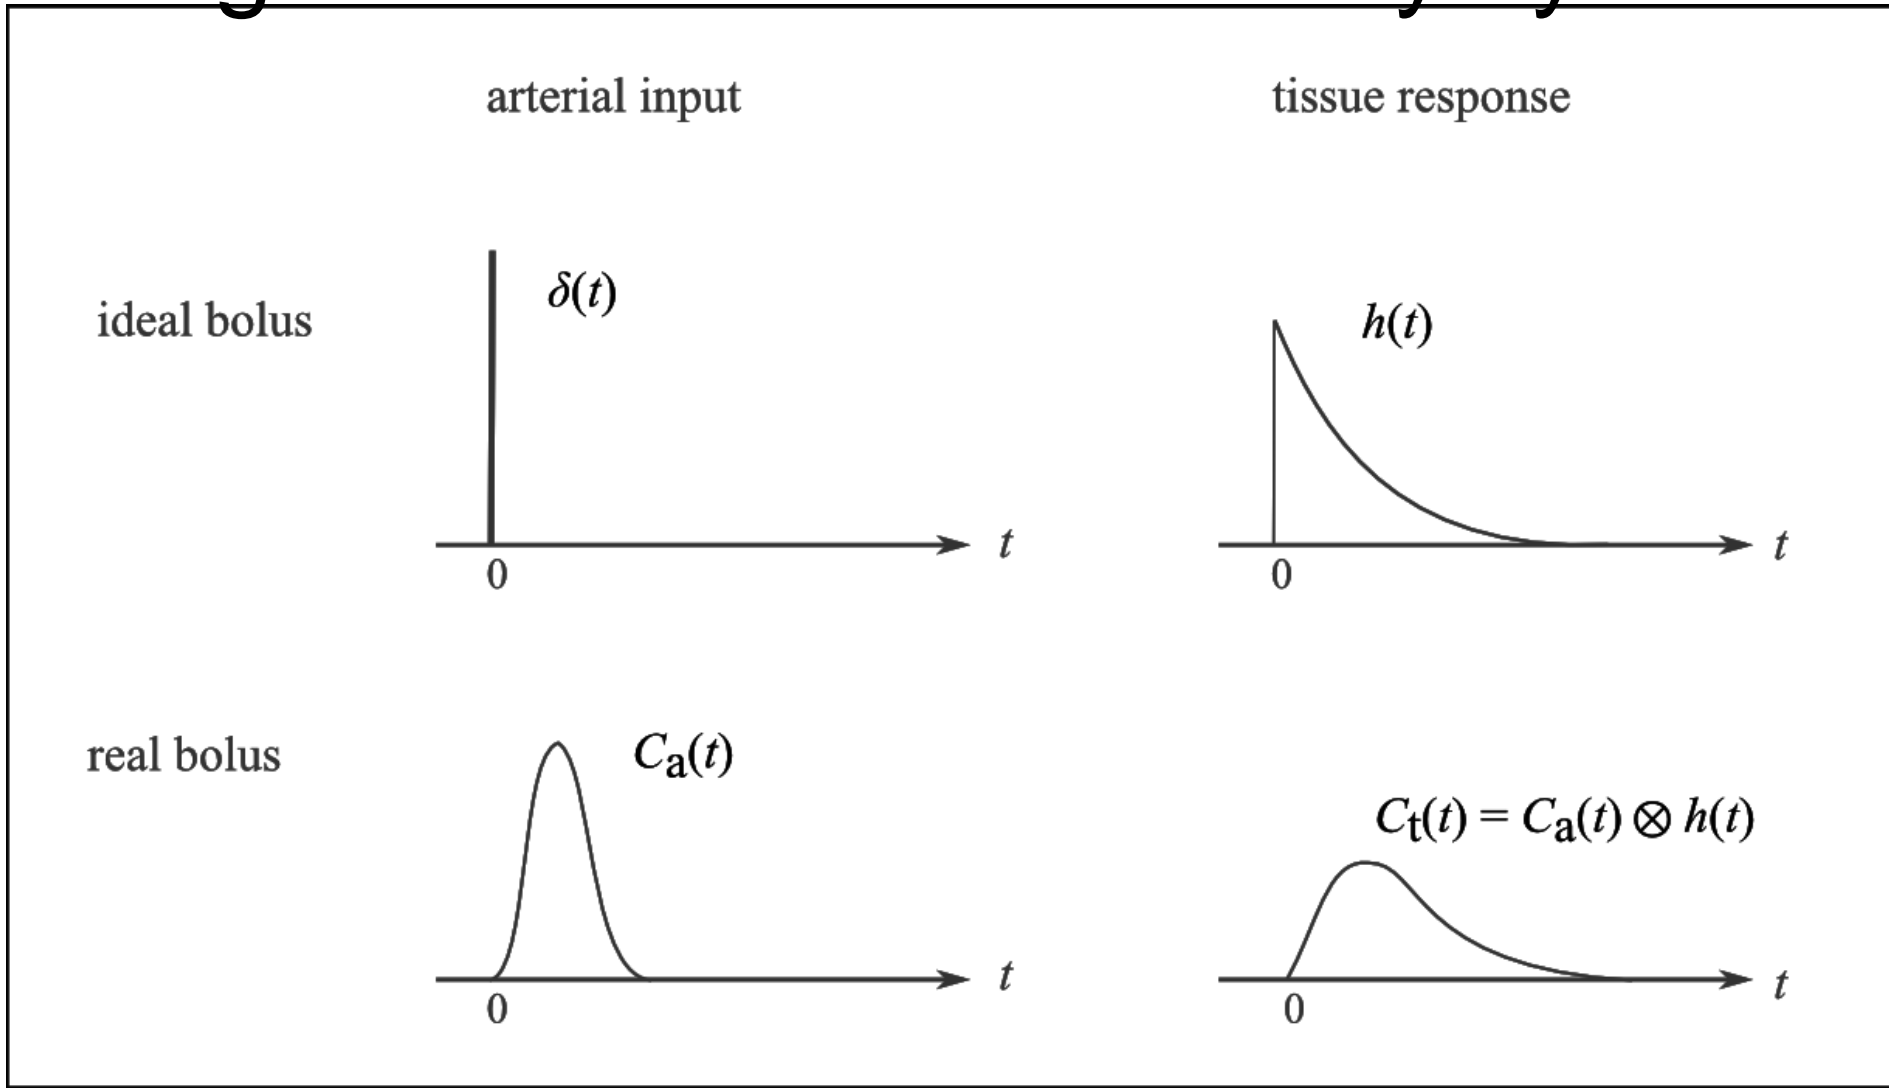

Physiological parameter:

K^{trans} : transfer constant (Vessel Permeability)

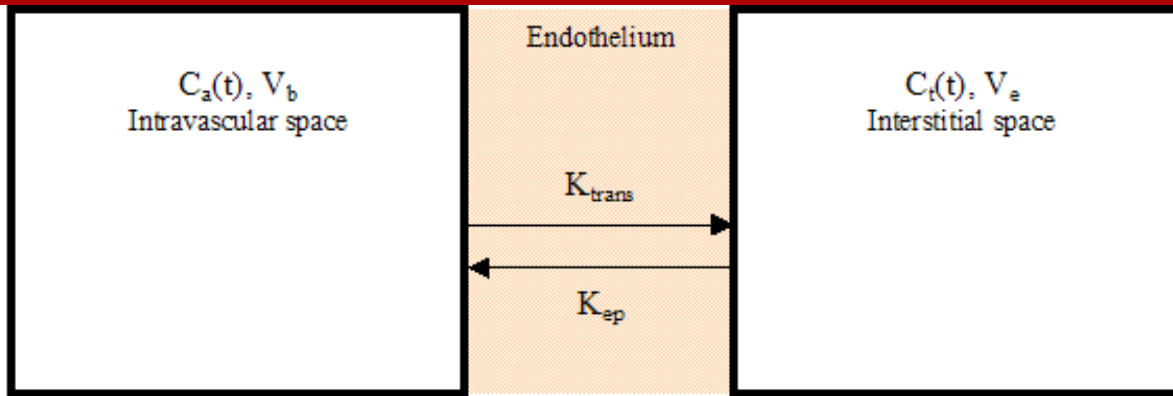

K_{ep} : reflux constant

V_e : extra-vascular, extra-cellular volume fraction (Cellular Density)

Diagram of a linear stationary system

- The Response to an ideal impulse $\delta(t)$ at the entrance is $h(t)$. The real bolus of an infusion is of a broadened form and thus the outflow response is given by a convolution of $C_a(t)$ and $h(t)$. (Modification of Brix et al).

Quantity	Definition	Unit
$C_a(t)$	Arterial concentration as a function of time	HU or mM
$C_t(t)$	Tissue concentration as a function of time	HU or mM
Hct	Hematocrit value	Dimensionless
K_{trans}	Transfer constant from the blood plasma into the EES	mL/g/min
k_{ep}	Transfer constant from the EES back to the blood plasma	1/min
t	Onset time of arterial contrast uptake	sec
V_b	Whole blood volume per unit of tissue	mL/g
V_e	Total EES volume ($V_e = K_{trans}/k_{ep}$)	mL/g

$$C_t(t) = \frac{K_{trans}}{1 - Hct} \left(C_a(t) \otimes e^{-k_{ep}(t-\tau)} \right)$$

DSC & DCE in neuro-oncological imaging

- Vascularity and vessel permeability of tumors
- Amplitude & exchange rates (k_{trans})
- Grading of primary brain tumors

rCBV
ml/100g
tissue

DSC & DCE in neuro-oncological imaging

Grading of primary brain tumors

DSC & DCE in neuro-oncological imaging

Detection of recurrent tumor

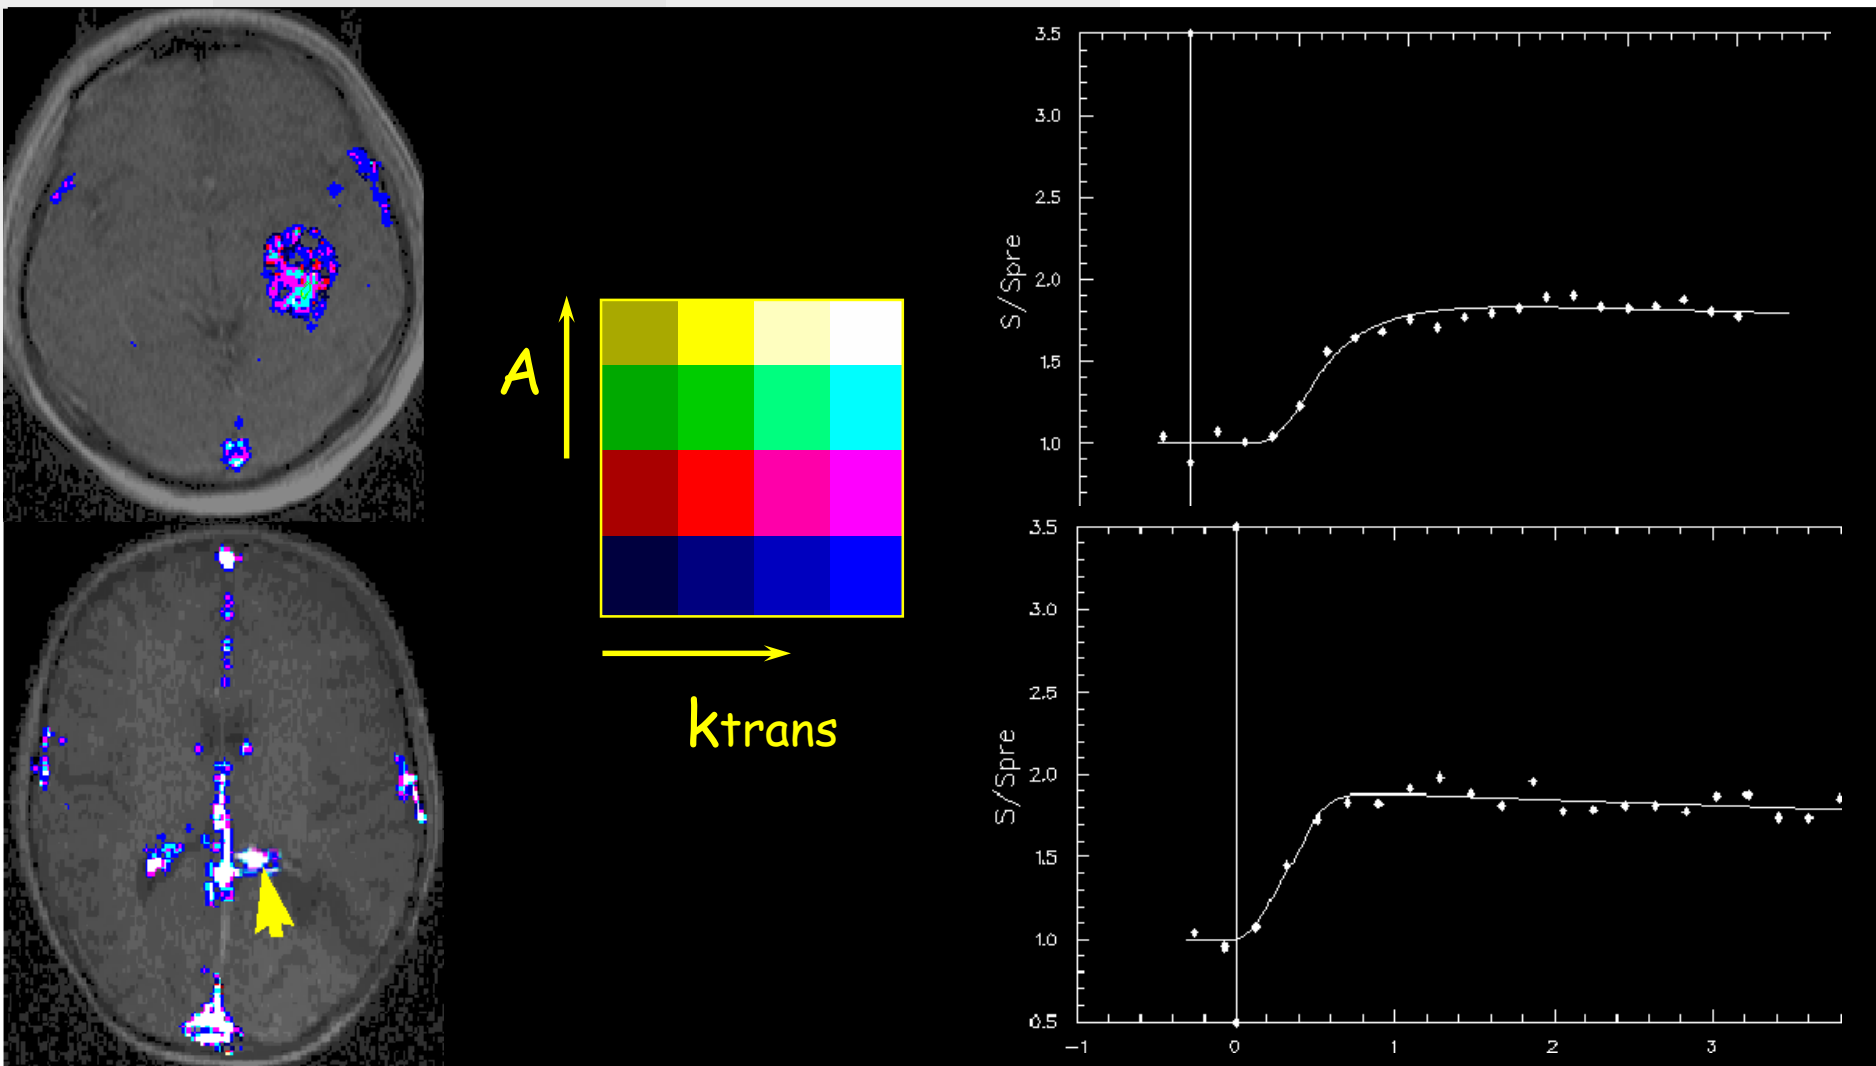

DSC & DCE in neuro-oncological imaging

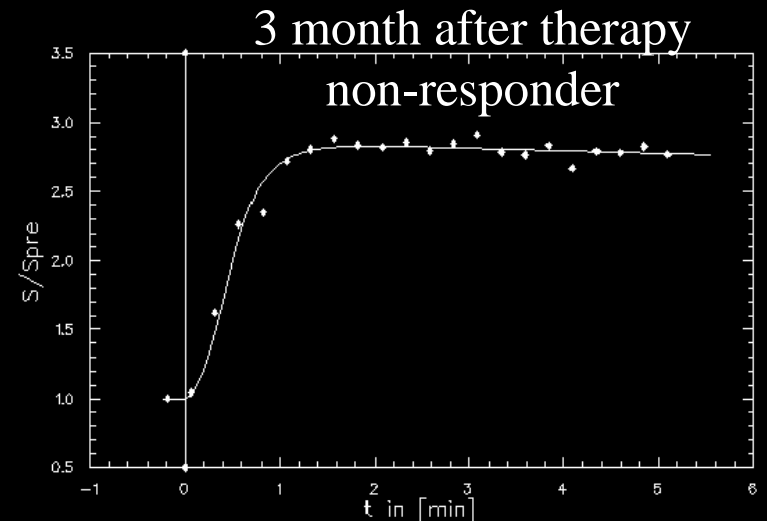

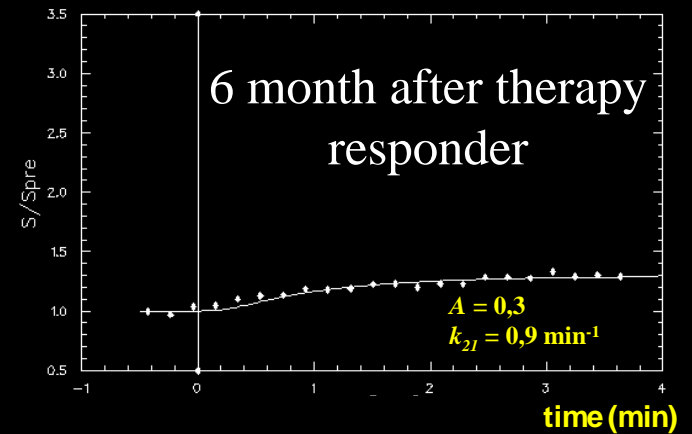

DCE in neuro-oncological imaging

Tumor characterisation & therapy response

DCE in neuro-oncological imaging

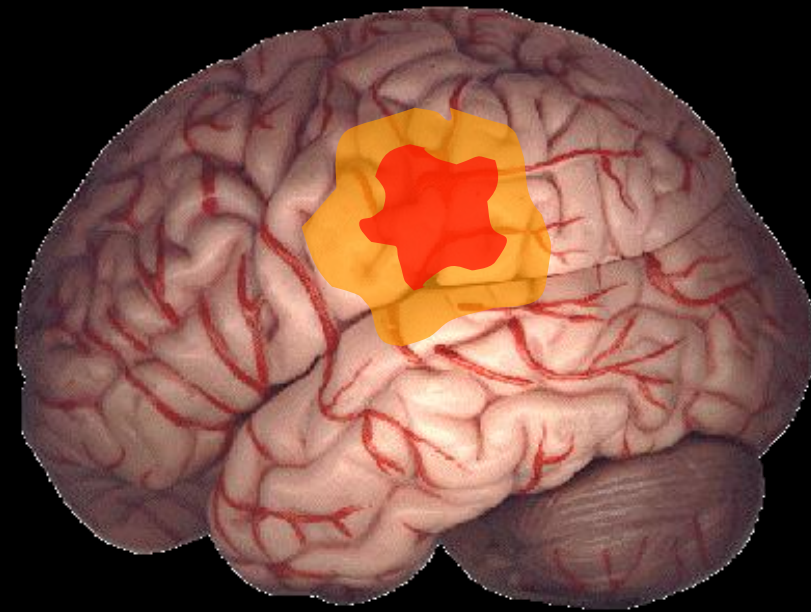

Tumor characterisation & therapy response

Stroke

„mismatch concept“

Infarct core ~ DWI

Penumbra ~ PWI – DWI

multimodal MRI protocol for stroke

Stroke

MRI protocol acute stroke

- Diffusion-MRI	0:52 min
- MRA (3D-TOF)	3:03 min
- FLAIR	3:20 min
- GRE T2/T2*	2:52 min
- CE-MRA	1 min
- Perfusion-MRI	1:30 min
- T1 + CA	2:30 min

total ~ 15 min

DSC in stroke imaging

How to define critically hypoperfused tissue ?

MTT > 3s

TTP > 4s

CBF < 40% compared to contra-side

CBV < 45% compared to c.s.

DSC in stroke imaging

M 57, recurrent TIAs

TOF-MRA

DWI

PWI

CT or DynaCT Perfusion

**Perfusion imaging: CBV
8s_DSA (Neuro PBV IR)**

**60 ml contrast 300 mg/ml, flow 4ml/s
60 ml saline, flow 4 ml/s**

DynaCT Perfusion

Perfusion: visualisation of CBV
MisMatch= MTT - CBV
